(54) Title: SEALABLE TRANSPORTABLE CONTAINER HAVING IMPROVED LATCH MECHANISM

(57) Abstract

A transportable, sealable container (18) for example a SMIF pod, has a box (20) and a box door (32). The box has a first sealing surface (54) and the box door has a second sealing surface (58) which forms a seal with the first sealing surface when the box door is moved in a sealing direction with respect to the box. A latch mechanism (101) provided in the box door is operable in two stages. The first stage of operation moves latch members (101₁, 101₂) from a retracted position to an extended position; in the retracted position the latch members are contained in the box door to allow movement of the box door with respect to the box, and in the extended position the latch members are adjacent to latch surfaces (112₁, 112₂) of the box. Movement from the retracted to the extended position is performed without contact between the latch members and the latch surfaces to avoid any scraping or rubbing action which would create particles in the "clean" interior region of the box. The second stage of operation engages latch members with the latch surfaces to move the box door in the sealing direction; this second stage of operation is also performed without scraping or rubbing of the latch members and the latch surfaces.

DESIGNATIONS OF "DE"

Until further notice, any designation of "DE" in any international application whose international filing date is prior to October 3, 1990, shall have effect in the territory of the Federal Republic of Germany with the exception of the territory of the former German Democratic Republic.

10 SEALABLE TRANSPORTABLE CONTAINER HAVING A PARTICLE FILTERING SYSTEM, Inventors: Mihir Parikh, Anthony C. Bonora, Serial No. 840,380, Filed: May 1, 1986, now U.S. Patent No. 4,724,874.

BACKGROUND OF THE INVENTION

Field of the Invention

15 The present invention relates to standardized mechanical interface (SMIF) systems for reducing particle contamination, and more particularly to transportable containers which are sealable to prevent influence of external factors on the contents of the 20 containers.

Description of the Related Art

A standardized mechanical interface (SMIF) system has been proposed by the Hewlett-Packard Company as disclosed in U.S. Patent No. 4,532,970 and 4,534,389.

25 The purpose of the SMIF system is to reduce particle fluxes onto wafers. This end is accomplished, in

-3-

part, by mechanically ensuring that during transportation and storage the gaseous media (such as air or nitrogen) surrounding the wafers is essentially stationary relative to the wafers and by ensuring that 5 particles from the ambient environment do not enter the immediate wafer environment. The SMIF concept is based on the realization that a small volume of controlled (with respect to motion, air flow direction and external contaminants), particle-free air provides a 10 clean environment for wafers. Further details of one proposed system are described in the article entitled "SMIF: A TECHNOLOGY FOR WAFER CASSETTE TRANSFER IN VLSI MANUFACTURING," by Mihir Parikh and Ulrich Kaempf, Solid State Technology, July 1984, pp. 111-115.

15 Systems of the above type are concerned with particle sizes which range from below 0.1 micrometers to above 200 micrometers. Particles with these sizes can be very damaging in semiconductor processing because of the small geometries employed in fabricating 20 semiconductor devices. Typical advanced semiconductor processes today employ geometries which are 1 micrometer and under. Unwanted contamination particles which have geometries measuring greater than 0.05 micrometers substantially interfere with 1 micrometer 25 geometry semiconductor devices. The trend, of course, is to have smaller and smaller semiconductor processing

-4-

geometries which today in research and development labs approach 0.5 micrometers and below. In the future, geometries will become smaller and smaller and hence smaller and smaller contamination particles become of interest.

A SMIF system has three main components: (1) minimum volume, sealed pods used for storing and transporting wafer cassettes; (2) canopies placed over cassette ports and wafer processing areas of processing equipment so that the environments inside the pods and canopies (after having clean air sources) become miniature clean spaces; and (3) a transfer mechanism to load/unload wafer cassettes from a sealed pod without contamination of the wafers in the wafer cassette from external environments.

Wafers are stored and transported in pods, and are transferred from a pod to a piece of processing equipment in the following manner. First, a pod is placed at the interface port on top of the canopy. Each pod includes a box and a box door designed to mate with doors on the interface ports of the processing equipment canopies. Then, latches release the box door and the canopy port door simultaneously; the box door and the interface port door are opened simultaneously so that particles which may have been on the external door surfaces are trapped ("sandwiched") between the

-5-

box and interface port doors. A mechanical elevator lowers the two doors, with the cassette riding on top, into the canopy covered space. A manipulator picks up the cassette and places it onto the cassette port/elevator of the equipment. After processing, the 5 reverse operation takes place.

The SMIF system has been proved effective by experiments using prototype SMIF components both inside and outside a clean room. The SMIF system provides at 10 least a ten-fold improvement over the conventional handling of open cassettes inside the clean room.

Conventional SMIF pods have the potential to create particles due to physical scraping of latch mechanisms against latch surfaces. Although few 15 particles are released during each latching operation, over the course of hundreds of processing steps for a wafer, the number of particles created each time the SMIF pod is latched and/or unlatched may build to a significant number.

20 In SMIF pods utilizing conventional latching systems, scraping occurs when a latch member and a latch surface, one or both of which have a sloped surface, move from a disengaged to a fully engaged orientation. The sealing surfaces on the box and the 25 box door are designed to seal upon application of pressure which forces these sealing surfaces together,

-6-

and thus the latch system must (a) prevent movement of the box door with respect to the box and (b) create a clamping force which forces the sealing surfaces together. The clamping force is generated by sliding 5 the latch surface along a sloped latch member or vice versa.

Latch mechanisms on conventional SMIF pods are usually provided on the box so that the latch mechanism may alternately be used to clamp the box door to the 10 box or to clamp the box to the port plate of a processing station. To provide this dual function, it is necessary to have notches or openings in the perimeter of the bottom of the box so that the latch mechanisms could move to engage either the box door or 15 the port plate. These openings provide access points through which contaminants may enter the "clean" environment.

In conventional SMIF pods, the latch mechanism supports the edges of the box door creating the 20 possibility that the box door will deflect (bow or bend) under the weight of the wafers resting on the box door in addition to the sealing forces, potentially creating leaks in the seal between the box and the box door. Further, conventional latch mechanisms for SMIF 25 pods may be subject to tampering which allows unauthorized access to the contents of the container.

-7-

SUMMARY OF THE INVENTION

It is, therefore, an object of the present invention to provide a sealable, transportable container having a latch mechanism which operates without any scraping or rubbing contact of the latch mechanism and portions of the container contacted by the latch mechanism.

10 A further object of the present invention is to provide a latch mechanism which supports the box door at positions which minimize deflection (or bowing) of the box door.

15 Another object of the present invention is to provide a transportable container in which the latch mechanism is tamper resistant to prevent unauthorized access to the contents of the container.

Another object of the present invention is to provide a SMIF pod having a latch mechanism which is centrally operated.

20 These and other objects of the present invention are provided by a latch mechanism which has motion in two directions and which moves in both directions without making scraping or rubbing contact with the box or box door in the clean, interior region of the box. The first direction of motion moves the latch mechanism 25 from a first retracted or bypass position, where the box and box door are free to move with respect to each

-8-

other so that the pod may be opened or closed, to a second or extended position, where the latch mechanism prevents the box door from moving with respect to the box. The sealing surfaces of the box and the box door 5 make sealable contact when the box door is moved in a sealing direction so that the sealing surface of the box door moves towards and contacts the sealing surface of the box. The second direction of motion of the latch mechanism is such that the latch mechanism 10 moves the box door in the sealing direction with respect to the box. Further, the latch mechanism supports the box door at points spaced from the periphery of the box door.

A sealable, transportable container in accordance 15 with the present invention comprises a box having a first sealing surface, a box door having a second sealing surface adapted to form a seal with said first sealing surface when said box door is moved in a sealing direction with respect to said box, and latch 20 means for motion in a first direction between a first position which allows motion of said box door with respect to said box, and a second position, which allows motion of said box door with respect to said box, and a second position, which limits the motion of 25 said box door with respect to said box, without scraping contact between said latch means and said box

-9-

or said box door in said interior region, and for motion in a second direction between said second position and a third position to move said box door in the sealing direction to bring said first and second 5 sealing surfaces into contact without scraping contact between said latch means and said box or said box door in said interior region.

A standardized mechanical interface (SMIF) pod in accordance with the present invention comprises a box 10 having an interior region, a first sealing surface, and at least two latch engaging surfaces; a box door having a second sealing surface which sealably mates with said first sealing surface when said box door is moved in a sealing direction with respect to said box 15 to isolate said interior region from ambient pressure conditions; a latch member provided in said box door, having at least two box engagement portions, and being movable between a disengaged position, an engaging position and an engaged position, whereby the latch 20 member is adapted to move from the disengaged position to the engaging position without contacting said box and whereby movement of said latch member from the engaging position to the engaged position causes said box engagement portions of said latch member to contact 25 said latch engaging surfaces without scraping said latch member against said latch engaging surfaces and

-10-

to move said box door in the sealing direction; and two-stage cam means for moving said latch member from the disengaged position to the engaging position in a first independent stage of operation and for moving 5 said latch plate from the engaging position to the engaged position in a second independent stage of operation.

These and other objects and advantages of the invention will appear more clearly from the following 10 description in which the preferred embodiments of the invention have been set forth in detail in conjunction with the drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1A is an isometric view of a processing 15 station having a canopy for receiving a SMIF pod;

Figs. 15A and B are side, isometric views of box doors showing different deflection patterns.

-12-

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention will be described in the context of a SMIF system for storing and transporting wafers and/or reticles. However, it is to be understood that a sealable, transportable container in accordance with the present invention may be used to store and transport many other inanimate objects as well as living objects such as laboratory animals.

The general structure of a SMIF pod and the mating of a SMIF pod with processing equipment are described in U.S. Patent No. 4,724,874 which is hereby incorporated by reference. However, for completeness, a brief description of the disclosure is provided herein.

Figs. 1 and 2 illustrate a processing station 8 having a canopy 10 which is an easily removable shield that covers the wafer handing mechanism of processing equipment 12. Equipment 12 may be, for example, a photo resist applicator, mask aligner, inspection station or any similar processing equipment. The canopy 10, which is constructed of transparent plastic such as acrylic or Lexan to facilitate visual inspection and/or maintenance within the canopy 10, encloses the handling mechanisms of the processing equipment 12 and a holder 14, such as a wafer cassette holding wafers 16. The environment within the

-13-

processing equipment is separately maintained and separately cleaned and therefore the equipment 12 need not be installed in a clean room.

A sealable, transportable container (or pod) 18 having a box (or box top) 20 having an interior region 21 and a box door 32 is mounted on the horizontal surface 22 of canopy 10 by a port assembly 24. The port assembly 24 includes a port plate 26, port door 28, and an elevator mechanism 30. Elevator mechanism 30 transports a cassette holder 14, containing the integrated circuit wafers 16 from the interior region 21 of box 20 into the region beneath the canopy 10. In Fig. 1B, port door 28 and box door 32 are shown in the closed position by the dotted lines. A mover assembly 34 includes a platform 36, a shaft engagement device 38 and a drive motor 40. The platform 36, extending from the elevator assembly 30, carries the port door 28, the box door 32 and the holder 14 in a vertical direction. The platform 36 is attached by engagement device 38 to a vertical guide 42 of elevator assembly 30.

Typically, guide 42 includes a lead screw (not shown) and the drive motor 40 drives a gear (not shown) which engages the lead screw for driving the platform 36 up or down. When the platform 36 is driven to the closed position, the port door 28 closes the port opening in the canopy 10.

-14-

In a similar manner, a manipulator assembly shown generally by the numeral 44 is fastened to a platform 46 which has an engagement means 48 for engaging the vertical guide 42. Manipulator assembly 44 includes a 5 manipulator arm 50 and an engagement head 52 adapted to engage holder 14. By vertical operation of the platforms 36 and 46 and by operation of the manipulator assembly 44, the holder 14 is moved from its position on the box door 32 to a position on the equipment 10 station 13 (as shown by the broken lines).

Fig. 2A is an exploded view of container 18 and port assembly 24. Container 18 can be alternately pressurized or evacuated when box 21 and box door 32 are sealed together to isolate the interior region of 15 box 21 from ambient conditions. Port plate 26 is connectable to a coaxial injector/extractor 50 at gas transfer valve 52 (Fig. 2B).

Fig. 2B shows container 18 mated to port assembly 24 of processing equipment 12. Container 18 is 20 designed for sealably mating with the port assembly 24, and thus box 20 has first and second box top sealing surfaces 54, 56, respectively. Box door 32 has a first box door sealing surface 58 for sealably mating with the first box top sealing surface 54, and gasket 55 25 between surfaces 54 and 58 provides a seal. Port plate 26 has first and second port plate sealing surfaces 60,

-15-

62, respectively. The first port plate sealing surface 60 sealably mates with the second box top sealing surface 56, making a second seal as gasket 57 is compressed.

5 Port door 28 has a first port door sealing surface 64 which sealably mates with the second port plate sealing surface 62; a third seal is provided by gasket 59. The box top 20 may include a conduit 63 defining a channel between valve 52 and the interior space 21 of 10 box 20. At one end of channel 66 is a filter 69 for filtering fluids (e.g., gasses) passing therethrough.

When the first, second and third seals are made, the interior space 21 of box 20 may be cleaned by alternately evacuating/pressurizing the interior space 15 21. In order to evacuate interior space 21, injection/extractor 50 is activated to withdraw fluid from interior space 21. As the fluids are withdrawn, they pass through filter 69, through channel 66 and through a coaxial valve (not shown) of 20 injection/extractor 50.

The port door 28 includes a latch actuating mechanism 66 having pins 70 for actuating the box door latch mechanism 80 and thereby releasing box door 32 from box 20. Wafers 16 can be moved by elevator 25 mechanism 30 and mover assembly 34 into the proper

-16-

position in the processing equipment 12 for processing without human intervention.

A latch mechanism for a SMIF pod in accordance with the present invention will be described with reference to Figs. 3-13. In the preferred embodiment, the latch mechanism is provided in box door 32 and centrally actuated, allowing a single latch actuating mechanism to release the box door 32 from the box 20. Alternatively, a latch mechanism in accordance with the present invention could be provided in box 20.

With reference to Fig. 3, box 20 includes a domed housing 90 and a ring-like engaging portion 92. Housing 90 and engaging portion 92 may be formed integrally, for example, by injection molding, or as separate components assembled to form box 20. A gasket 120, which provides the seal between box 20 and box door 32 resides in a gasket-retaining slot 122 in box door 32. In the preferred embodiment, a liner (not shown) is provided on door 32 and gasket 120 contacts the liner. The liner is a removable element which may be formed of, for example, plastic materials which do not outgas or introduce particles, as described in U.S. Patent No. 4,739,882, which is hereby incorporated by reference. The liner may also be formed of a material which provides the capability of dissipating or preventing the formation of static charges. Latch

-17-

mechanism 80 is housed in base 32 and latch mechanism 80 protrudes from box door 32 through windows 94 to engage latch engaging surfaces 112₁₋₈ (Figs. 8-9) of box 20.

5 The two-stage rotary cam latch mechanism 80 of the present invention includes first and second latch plates 101₁₋₂, a cam mechanism 103 pivotally mounted on box door 32, and latch plate supports 105₁₋₆. The operation of latch mechanism 80 is a two-stage 10 operation which is illustrated in Figs. 4-7 and 10-11. In the first stage of operation, cam mechanism 103 slides latch plates 101₁₋₂ linearly, and in the second stage, cam mechanism 103 causes latch plates 101₁₋₂ to pivot on latch plate supports 105₁₋₆.

15 Each latch plate 101₁₋₂ has at least one box-engaging portion; in the preferred embodiment of the present invention, designed for use in a pod for storing and transporting 200mm wafers, each latch plate 101₁₋₂ has two latch arms 108₁₋₂ and 108₃₋₄, 20 respectively. Latch arms 108₁₋₄ each have two latch fingers 110₁₋₈ which engage respective ones of latch engaging surfaces 112₁₋₈ of box 20.

25 The first stage of the latching operation involves moving latch plates 101₁₋₂ from retracted (or disengaged) positions (Fig. 4) where the latch plates 101₁₋₂ are entirely contained within box door 32 to

-18-

extended (or engaging) positions (Fig. 5) where latch fingers 110₁₋₈ extend out of box door 32 and are adjacent to latch engaging surfaces 112₁₋₈ of box 20. In the first stage when the latch plates 101₁₋₂ move 5 from the retracted position to the extended position in a plane parallel to the plane of box door 32, latch fingers 110₁₋₈ do not contact latch engaging surfaces 112₁₋₈. Accordingly, there are no particles created by scraping or rubbing of the latch fingers 110₁₋₈ against 10 the latch engaging surfaces 112₁₋₈.

The second stage of the latching operation involves substantially vertical motion of latch fingers 110₁₋₈. "Vertical motion" refers to motion in a direction perpendicular to the plane of box door 32, 15 and to the plane of motion of latch plates 101₁₋₂ during the first stage of the latching operation. The motion of latch fingers 110₁₋₈ during the second stage engages latch fingers 110₁₋₈ with respective ones of latch engaging surfaces 112₁₋₈, and creates a latching 20 and/or clamping force which sealably mates a first sealing surface of box 20 with second sealing surface of box door 32. The first sealing surface comprises knife edge 118 on box 20, and the second sealing surface comprises gasket-retaining slot 122 in box door 25. A gasket 120 sits in gasket-retaining slot 122 and forms the seal between box 20 and box door 32. Gasket

-19-

120 is preferably fabricated from a resilient, compressible material which does not release particles when contacted and compressed by knife edge 118 or outgas. Fig. 8A illustrates engaging portion 92 of box 5 20 in a plan view and Figs. 8B and 8C illustrate knife edge 118 in cross section. As discussed above, a liner may be provided between box door 32 and gasket 120.

Latch mechanism 80 resides in a cavity 124 in box door 32. Accordingly, any particles generated by the 10 interaction of cam mechanism 103 and latch plates 101₁₋₂ and/or latch plates 101₁₋₂ and latch plate supports 105₁₋₆ are contained in cavity 124. Additionally, it is possible to add a port in box door 32 so that cavity 124 may be evacuated in order to remove any particles 15 which are created in cavity 124.

The details of the construction and operation of cam mechanism 103 will be described with reference to Figs. 6, 7, 10, 11, 12 and 13. Cam mechanism 103 is a two-stage cam mounted on a pivot post 130 (Figs. 20 10-11); pivot post 130 is attached to the top surface 32a of box door 32. First and second holes 132₁₋₂ in cam mechanism 103 engage pins 70 of latch actuating mechanism 66. First and second slots 134₁₋₂ are provided in bottom wall 32b of box door 32 to enable 25 pins 70 to engage cam holes 132₁₋₂.

-20-

The two stages of operation of cam mechanism 103 and latch plates 101_{1-2} occur as follows. In the first phase of the latching operation, cam lobes 136_{1-2} engage camming surfaces 138_{1-2} (Figs. 6-7), 5 respectively of latch plates 101_{1-2} . As cam mechanism 103 rotates through an angle of approximately 40° from an unlatched to an intermediate position, cam lobes 136_{1-2} cause latch plates 101_{1-2} to move from the retracted to the extended position. In order to 10 maintain latch plates 101_{1-2} in a plane parallel to the plane of box door 32 during the sliding operation of the first stage of the latching operation, latch plate springs 140_{1-2} (Figs 10-11) are attached to respective ones of latch plates 101_{1-2} and force the cam arms 109_{1-2} of respective ones of latch plates 101_{1-2} 15 towards cam mechanism 103. The biasing force provided by springs 140_{1-2} causes rollers 142_{1-2} of respective ones of latch plates 101_{1-2} to contact roller surface 144 of cam mechanism 103. 20 Risers 146_{1-2} (Figs. 10-13) are provided on roller surface 144 of cam mechanism 103. As cam mechanism 103 rotates beyond the first 40° of motion from the intermediate position to a latched position, linear motion of latch plates 101_{1-2} ceases and rollers 142_{1-2} 25 begin riding up respective ones of risers 146_{1-2} . As rollers 142_{1-2} ride up risers 146_{1-2} , latch plates

-21-

101₁₋₂ pivot about an axis defined by the contact points of latch plate 101₁ and a first group of latch plate supports 105₁₋₃ and of latch plate 101₂ and a second group of latch plate supports 105₄₋₆. The pivoting motion of latch plates 101₁₋₂ causes latch fingers 110₁₋₈ to move substantially vertically without scraping motion of latch fingers 110 and latch surfaces 112. For the latch mechanism of the present invention, where latch plate supports 105₁₋₆ are approximately 10 2-1/4" from fingers 110 when the latch plates 101₁₋₂ are in the intermediate position and move vertically approximately 0.054" from the intermediate to the latched position, experimental results have shown that latch fingers 110 undergo horizontal motion of only 15 approximately 0.001". This minimal amount of horizontal motion prevents generation of particles by scraping.

In the unlatching operation rollers 142₁₋₂ ride back down risers 146₁₋₂ as cam mechanism 103 is rotated 20 in the opposite direction. Springs 140₁₋₂ provide the biasing force to keep rollers 140₁₋₂ in contact with risers 146₁₋₂. After rollers 140 come in contact with roller surface 144, cam lobes 136₁₋₂ engage cam surfaces 138₁₋₂ of latch plates 101₁₋₂ and move latch plates 101₁₋₂ from the extended to the retracted 25 position.

-22-

When latch plates 101₁₋₂ and cam mechanism 103 are in the latched position, cam lobes 136₁₋₂ are aligned with the axis of rotation of cam mechanism 103. Accordingly, any force tending to move the latch plates 5 101₁₋₂ from the extended to the retracted position is transmitted along cam lobes 136₁₋₂ through the rotational axis of cam mechanism 103 without creating any torque which would rotate cam mechanism 103 from the latched position. Thus, cam lobes 136₁₋₂ 10 physically maintain latch plates 101 in the extended position both during the second stage of the latching operation and when the latch mechanism is in the latched orientation, preventing the latch from releasing under the application of linear impacts.

15 The second stage of the latching operation provides a strong clamping force to engage knife edge 118 with gasket 120 in order to effect a seal which prevents external conditions from affecting the interior region 21 of pod 18. For example, this seal 20 prevents particulate matter and moisture from entering interior region 21. Further, this seal allows the interior region 21 to be evacuated and back-filled with an insert gas. The clamping force is approximately one (1) pound per linear inch. This clamping force is 25 regulated by a slight bowing or spring action of latch plates 101₁₋₂. This bowing is designed into latch

-23-

plates 101_{1-2} which are formed of 0.125-inch thick aluminum alloy, for example, 7075-T6.

In order to prevent localized bending or deflection of the box door 32, due to the application of the clamping force, the clamping loads are distributed. One aspect to the distribution of the clamping force is the use of multiple latch arms 108_{1-4} for each latch plate 101_{1-2} . Latch arms 108_{1-4} are positioned at points which are half the distance from the center to the end of the edge of the box door. As shown in Fig. 5, for a box door having a width W , latch arms are a distance approximately $W/2$ from each other and a distance approximately $W/4$ from the edge of the box door.

To strengthen the latch engaging areas of the box 20, which is usually formed of plastic, a post 113 is provided between each pair of latch engaging surfaces 112_{1-8} . To accommodate post 113, each latch arm 108_{1-4} has latch fingers 110_{1-8} separated by a notch. Post 20 113 serves to decrease the unsupported length of the latch engaging surfaces 112_{1-8} by a factor of approximately one third and to increase the shear area by a factor of 2.

Figs. 14A and 15A diagrammatically illustrate the deflection D_A of a box door supported only at its edges, i.e., at support points 200_{1-4} and having a load

-24-

(FW_{1-n}) created by the wafers stored in the pod uniformly distributed over the area of the box door. In addition, a sealing force FS is applied at the periphery of the box door. Any section of the box door 5 along length L can be treated as a beam and the maximum deflection D_A at the center varies with L³. The deflections and stresses in loaded beams are known phenomena discussed in, for example, MACHINERY'S HANDBOOK, Obery and Jones, Industrial Press, 1963. If 10 the amount of deflection D_A is too large, the seal between the box door and the box may be broken.

Figs. 14B and 15B diagrammatically illustrate that the maximum deflection D_B of a box door in accordance with the present invention is greatly 15 reduced with respect to the deflection D_A of a box door supported only at its edges. In the box door of the present invention, the load of the wafers (FW) and the sealing force (FS) on the box door is supported at the positions of latch plate supports 105₁₋₆. Latch plate 20 supports 105₁₋₆ are located a distance A from the edge (or periphery) of the box door. Treating each section of the box door along length L as a beam, the maximum deflection D_B at the center varies with B² (B²-A²)/L. The application of the sealing forces FS to a 25 cantilevered portion of the box door counters the deflection of the box door caused by the weight of the

-25-

wafers. It has been determined that D_B for the box door of the present invention is approximately one tenth (1/10) of D_A . The distribution of latch plate supports 105 along the width of box door 32 prevents 5 deflections along the width.

The latch mechanism 80 of the present invention does not require any interruptions of the perimeter of the base of box 20, thereby removing areas of access to the "clean" environment within box 20. Further, the 10 entire latch mechanism is contained in box door 32 which facilitates cleaning of box 20. Tampering with latch mechanism 80 is virtually eliminated, due to the fact that forces intended to move the latch plates 101 from the extended to the retracted position do not 15 rotate cam mechanism 103 and due to the fact that cam mechanism 103 is contained within cavity 124 of box door 32 so that unauthorized access would require rotating cam mechanism 103 by inserting an implement into cam holes 132. Accordingly, access can be limited 20 by the use of an interlock system which must be activated and/or mechanical keys which must be inserted before rotation of cam mechanism 103 is possible.

The many features and advantages of the present invention will be apparent to those skilled in the art 25 from the Description of the Preferred Embodiments and the Drawings. Accordingly, the following claims are

-26-

intended to cover all modifications and equivalents
falling within the scope of the invention.

-27-

CLAIMS

What is claimed is:

1. A sealable, transportable container, comprising:

a box having an interior region and a first sealing surface;

a box door having a second sealing surface adapted to mate with said first sealing surface when said box door is moved in a sealing direction; and

latch means for non-scraping motion in a first direction between a first position, which allows motion of said box door with respect to said box, and a second position, which limits the motion of said box door with respect to said box, and for non-scraping motion in a second direction between said second position and a third position, to move said box door in the sealing direction and to bring said first and second sealing surfaces into contact.

2. A sealable, transportable container, comprising:

a box having an interior region and a first sealing surface;

a box door having a second sealing surface adapted to mate with said first sealing surface when said box door is moved in a sealing direction; and

latch means for:

-28-

motion in a first direction between a first position, which allows motion of said box door with respect to said box, and a second position, which limits the motion of said box door with respect to said box, without scraping contact between said latch means and said box or said box door in said interior region, and,

motion in a second direction between said second position and a third position, without scraping contact between said latch means and said box or said box door in said interior region, to move said box door in the sealing direction and to bring said first and second sealing surfaces into contact.

3. A sealable, transportable container, comprising:

a box having a first sealing surface;

a box door having a second sealing surface adapted to mate with said first sealing surface when said box door is moved in a sealing direction;

latch means mounted on said box door for motion in a first direction between a first position, in which said latch means bypasses said box when said box door is moved with respect to said box, a second position, in which said latch means limits the motion of said box door with respect to said box, and a third position, whereby motion of said latch means from the

-29-

first position to the second position occurs without sliding contact between said latch means and said box, and for motion in a second direction from the second position to a third position to move said box door in the sealing direction without sliding contact between said latch means and said box;

latch actuating means for moving said latch means from the first position to the second position and for moving said latch means from the second position to the third position.

4. A sealable, transportable container according to claim 3, wherein:

said latch means contacts said box when said latch means is in the third position; and

said latch means, when in the third position, supports said box door at positions spaced from the periphery of said box door to prevent deflection of said box door.

5. A sealable, transportable container according to claim 4, wherein:

said latch means comprises first and second latch members; and

said latch actuating means is centrally positioned in said box door and moves both said first and second latch members.

-30-

6. A standardized mechanical interface (SMIF) pod, comprising:

a box having an interior region, a first sealing surface, and at least two latch engaging surfaces;

a box door having a second sealing surface;

means for mating with said first and second sealing surfaces to provide a seal which isolates said interior region from ambient pressure conditions when said box door is moved in a sealing direction with respect to said box;

first and second latch members provided in said box door, each latch member having at least two box engagement portions and being movable between a disengaged position, an engaging position and an engaged position, whereby said latch members are adapted to move from the disengaged position to the engaged position without contacting said box and whereby movement of said latch members from the engaging position to the engaged position causes said box engagement portions of said latch members to contact said latch engaging surfaces without scraping said latch members against said latch engaging surfaces and to move said box door in the sealing direction; and

two-stage cam means centrally located in said box door for moving said latch members from the disengaged position to the engaging position in a first

-31-

independent stage of operation and for moving said latch members from the engaging position to the engaged position in a second independent stage of operation.

7. A sealable, transportable container according to claim 6, wherein:

 said latch members contact said box when said latch member is in the engaged position; and

 said latch members, when in the engaged position, support said box door at positions spaced from the periphery of said box door to prevent deflection of said box door.

8. A transportable container for maintaining the cleanliness of articles to be processed, comprising:

 a box defining an interior space for containing the articles, said box having a box sealing surface and at least two latch surfaces;

 a box door having a box door sealing surface; means for mating with said box and box door sealing surfaces to provide a seal which isolates said interior region from ambient pressure conditions when said box door is moved in a sealing direction with respect to said box;

 at least two latch arms each having a box engaging portion, each said latch arm being mounted in said box door for movement, without contacting said box, between

-32-

a retracted position in which the latch arm is entirely contained within said box door and an extended position in which said box engaging portions of said latch arms are adjacent to respective ones of said latch surfaces and for movement between the extended position and a latched position without scraping said latch arms against said latch surfaces;

first means for supporting said latch arms in said box door for linear and pivoting motion; and

second means for moving said latch arms, in motion in a first plane substantially parallel to said box door sealing surface, from the retracted position to the extended position and for pivoting said latch arms from the extended position to the latched position so that said box engaging portions of said latch arms move in a direction substantially perpendicular to said first plane to move said box door in said sealing direction.

9. A transportable container according to claim 8, wherein:

said first means comprises first and second groups of latch arm support members provided on said box door at positions spaced from the periphery of said box door;

said first group of latch support members supports said first latch arm; and

-33-

said second group of latch support members supports said second latch arm.

10. A transportable container according to claim 8, wherein said second means comprises a two stage rotary cam, having at least two first stage camming surfaces and at least two second stage camming surfaces, rotatably mounted in the center of said box door so that rotation of said cam from a first position to a second position engages said first stage camming surfaces with and moves respective ones of said latch arms from the retracted position to the extended position and so that rotation of said cam from the second position to a third position engages said second stage camming surfaces with and pivots respective ones of said latch arms from the extended position to the latched position.

11. A SMIF system for maintaining the cleanliness of articles to be processed, comprising:

a SMIF pod defining an interior space for containing the articles, comprising:

a box having first and second box top sealing surfaces,

a box door having a box door sealing surface, a gasket for mating with said first box top sealing surface and said box door sealing surface to provide a seal which isolates said interior region from

-34-

ambient pressure conditions when said box door is moved in a sealing direction with respect to said box,

at least two latch arms each having a box engaging portion, each said latch arm being mounted in said box door for movement, without contacting said box, between a retracted position in which the latch arm is entirely contained within said box door and an extended position in which said box engaging portions of said latch arms are adjacent to respective ones of said latch surfaces and for movement between the extended position and a latched position,

first means for supporting said latch arms in said box door for linear and pivoting motion, and

second means for linearly moving said latch arms from the retracted position to the extended position and for pivoting said latch arms from the extended position to the latched position so that said box engaging portions of said latch arms move said box door in the sealing direction to make the first seal;

a port plate having first and second port plate sealing surfaces, said first port plate sealing surface sealably mating with the second box top sealing surface for making a second seal; and

a port door having a first port door sealing surface for sealably mating with the second port plate

-35-

sealing surface for making a third seal, the port door including means for operating said second means.

12. A SMIF system according to claim 11, further comprising:

conduit means for communicating between the interior space and an environment external to the box; and

filter means for filtering fluids passing through the conduit means.

13. A SMIF system for maintaining the cleanliness of articles to be processed, comprising:

a box defining an interior space for containing the articles, said box having first and second box top sealing surfaces;

a box door having a first box door sealing surface sealably mating with the first box top sealing surfaces for making a first seal;

box door latch means for latching the box door to the box top whereby said first seal is made and released by operation of the box door latch means, comprising:

a latch plate, provided in said box door, having at least two box engagement portions, and being movable between a disengaged position, an engaging position and an engaged position, whereby movement of said latch plate from the engaging position to the

-36-

engaged position causes said box engagement portions of said latch plate to contact said latch engaging surfaces moving said box door towards said interior region of said box and forcing said first and second sealing surfaces together to form a seal isolating said interior region from ambient pressure conditions, and

two stage cam means for moving said latch plate from the disengaged position to the engaging position without contacting said latch plate to the box in a first independent stage of operation and for moving said latch plate from the engaging position to an engaged position in a second independent stage of operation;

conduit means for communicating between the interior space and an environment external to the box;

filter means for filtering fluids passing through the conduit means;

a processing station, comprising:

a port plate having first and second port plate sealing surfaces, the first port plate sealing surface sealably mating with the second box top sealing surface for making a second seal;

a port door having a first port door sealing surface for sealably mating with the second port plate sealing surface for making a third seal, said port door

-37-

including means for activating the box door latch means; and

means for moving fluids into and out of the box through the filtering means, the means for moving fluids being in communication with the conduit means, whereby upon activation of the fluid moving means, the interior space is alternatively evacuated or pressurized.

AMENDED CLAIMS

[received by the International Bureau
on 5 October 1990 (05.10.90);
original claims 1-13 replaced by amended claims 1-13 (11 pages)]

1. A sealable, transportable container,
comprising:

a box having an interior region and a first
sealing surface;

a box door having a peripheral edge and a
second sealing surface adapted to mate with said first
sealing surface when said box door is moved in a sealing
direction; and

latch means for non-scraping motion in a first
direction between a first position, which allows motion
of said box door with respect to said box, and a second
position, which limits the motion of said box door with
respect to said box, and for non-scraping motion in a
second direction between said second position and a
third position, in which said latch means supports said
box door at positions spaced from said peripheral edge
of said box door to prevent said box door from
deflecting, to move said box door in the sealing
direction and to bring said first and second sealing
surfaces into contact.

2. A sealable, transportable container,
comprising:

a box having an interior region and a first
sealing surface;

a box door having a second sealing surface adapted to mate with said first sealing surface when said box door is moved in a sealing direction; and latch means for:

linear motion in a first direction between a first position, which allows motion of said box door with respect to said box, and a second position, which limits the motion of said box door with respect to said box, without scraping contact between said latch means and said box or said box door in said interior region, and,

pivoting motion in a second direction between said second position and a third position, without scraping contact between said latch means and said box or said box door in said interior region, to move said box door in the sealing direction, to bring said first and second sealing surfaces into contact.

3. A sealable, transportable container, comprising:

a box having a first sealing surface;

a box door having a peripheral edge and a second sealing surface adapted to mate with said first sealing surface when said box door is moved in a sealing direction;

latch means mounted on said box door for motion in a first direction between a first position, in

which said latch means bypasses said box when said box door is moved with respect to said box, a second position, in which said latch means limits the motion of said box door with respect to said box, and a third position, whereby motion of said latch means from the first position to the second position occurs without sliding contact between said latch means and said box, and for motion in a second direction from the second position to a third position, in which said latch means contacts said box and supports said box door at positions spaced from said peripheral edge of said box door to prevent deflection of said box door, to move said box door in the sealing direction without sliding contact between said latch means and said box;

latch actuating means for moving said latch means from the first position to the second position and for moving said latch means from the second position to the third position.

5. A sealable, transportable container according to claim 3, wherein:

said latch means comprises first and second latch members; and

said latch actuating means is centrally positioned in said box door and moves both said first and second latch members.

6. A standardized mechanical interface (SMIF) pod, comprising:

a box having an interior region, a first sealing surface, and at least two latch engaging surfaces;

a box door having a second sealing surface;

means for mating with said first and second sealing surfaces to provide a seal which isolates said interior region from ambient pressure conditions when said box door is moved in a sealing direction with respect to said box;

first and second latch members provided in said box door, each latch member having at least two box engagement portions and being, movable between a disengaged position, an engaging position and an engaged position, whereby said latch members are adapted to move from the disengaged position to the engaged position without contacting said box and whereby movement of said latch members from the engaging position to the engaged position causes said at least two box engagement portions of said latch members to contact respective ones of said at least two latch engaging surfaces without scraping said latch members against said at least two latch engaging surfaces and to move said box door in the sealing direction; and

two-stage cam means centrally located in said box door for moving said latch members from the disengaged position to the engaging position in a first independent stage of operation and for moving said latch

members from the engaging position to the engaged position in a second independent stage of operation.

7. A sealable, transportable container according to claim 6, wherein:

 said latch members contact said box when said latch member is in the engaged position; and

 said latch members, when in the engaged position, support said box door at positions spaced from the periphery of said box door to prevent deflection of said box door.

8. A transportable container for maintaining the cleanliness of articles to be processed, comprising:

 a box defining an interior space for containing the articles, said box having a box sealing surface and a plurality of latch surfaces;

 a box door having a box door sealing surface; means for mating with said box and box door sealing surfaces to provide a seal which isolates said interior region from ambient pressure conditions when said box door is moved in a sealing direction with respect to said box;

 a plurality of latch arms corresponding to respective ones of said latch surfaces, each said latch arm having a box engaging portion and being mounted in said box door for movement, without contacting said box, between a retracted position in which each of said plurality of latch arms is entirely contained within

said box door and an extended position in which said box engaging portion of each of said plurality of latch arms is adjacent to respective ones of said plurality of latch surfaces and for movement between the extended position and a latched position without scraping said plurality of latch arms against said plurality of latch surfaces;

first means for supporting said plurality of latch arms in said box door for linear and pivoting motion; and

second means for moving said plurality of latch arms, in substantially linear motion in a first plane substantially parallel to said box door sealing surface, from the retracted position to the extended position and for pivoting said plurality of latch arms from the extended position to the latched position so that said box engaging portions of said plurality of latch arms move in a direction substantially perpendicular to said first plane to move said box door in said sealing direction.

9. A transportable container according to claim 8, wherein:

said plurality of latch arms comprises a first latch arm and a second latch arm;

said first means comprises first and second groups of latch arm support members provided on said box

door at positions spaced from the periphery of said box door;

 said first group of latch support members supports said first latch arm; and

 said second group of latch support members supports said second latch arm.

10. A transportable container according to claim 8, wherein said second means comprises a two stage rotary cam, having at least two first stage camming surfaces and at least two second stage camming surfaces, rotatably mounted in the center of said box door so that rotation of said cam from a first position to a second position engages respective ones of said at least two first stage camming surfaces with and moves respective ones of said latch arms from the retracted position to the extended position and so that rotation of said cam from the second position to a third position engages respective ones of said at least two second stage camming surfaces with and pivots respective ones of said latch arms from the extended position to the latched position.

11. A SMIF system for maintaining the cleanliness of articles to be processed, comprising:

 a SMIF pod defining an interior space for containing the articles, comprising:

 a box having first and second box top sealing surfaces, and latch surfaces,

a box door having a box door sealing surface,

a gasket for mating with said first box top sealing surface and said box door sealing surface to provide a seal which isolates said interior region from ambient pressure conditions when said box door is moved in a sealing direction with respect to said box,

latch arms, each said latch arm having a box engaging portion, each said latch arm being mounted in said box door for movement, without contacting said box, between a retracted position in which said latch arms are entirely contained within said box door and an extended position in which said box engaging portion of each said latch arm is adjacent to respective ones of said latch surfaces and for movement between the extended position and a latched position,

first means for supporting said latch arms in said box door for linear and pivoting motion, and

second means for linearly moving said latch arms from the retracted position to the extended position and for pivoting said latch arms from the extended position to the latched position so that said box engaging portions of said latch

arms move said box door in the sealing direction to make the first seal;

a port plate having first and second port plate sealing surfaces, said first port plate sealing surface sealably mating with the second box top sealing surface for making a second seal; and

a port door having a first port door sealing surface for sealably mating with the second port plate sealing surface for making a third seal, the port door including means for operating said second means.

12. A SMIF system according to claim 11, further comprising:

conduit means for communicating between the interior space and an environment external to the box; and

filter means for filtering fluids passing through the conduit means.

13. A SMIF system for maintaining the cleanliness of articles to be processed, comprising:

a box defining an interior space for containing the articles, said box having first and second box top sealing surfaces and latch engaging surfaces;

a box door having a first box door sealing surface sealably mating with the first box top sealing surfaces for making a first seal;

box door latch means for latching the box door to the box top whereby said first seal is made and released by operation of the box door latch means, comprising:

a latch plate, provided in said box door, having at least two box engagement portions, and being movable between a disengaged position, an engaging position and an engaged position, whereby movement of said latch plate from the engaging position to the engaged position causes said at least two box engagement portions of said latch plate to contact said latch engaging surfaces moving said box door towards said interior region of said box and forcing said first and second sealing surfaces together to form a seal isolating said interior region from ambient pressure conditions, and

two stage cam means for moving said latch plate from the disengaged position to the engaging position without contacting said latch plate to the box in a first independent stage of operation and for moving said latch plate from the engaging position to an engaged position in a second independent stage of operation;

conduit means for communicating between the interior space and an environment external to the box;

filter means for filtering fluids passing through the conduit means;

a processing station, comprising:

a port plate having first and second port plate sealing surfaces, the first port plate sealing surface sealably mating with the second box top sealing surface for making a second seal;

a port door having a first port door sealing surface for sealably mating with the second port plate sealing surface for making a third seal, said port door including means for activating the box door latch means; and

means for moving fluids into and out of the box through the filtering means, the means for moving fluids being in communication with the conduit means, whereby upon activation of the fluid moving means, the interior space is alternatively evacuated or pressurized.

V. OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE 1

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. Claim numbers . because they relate to subject matter ¹² not required to be searched by this Authority, namely:

2. Claim numbers . because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out ¹³, specifically:

3. Claim numbers . because they are dependent claims not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI. OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING 2

This International Searching Authority found multiple inventions in this international application as follows:

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

4. As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

Remark on Protest

- The additional search fees were accompanied by applicant's protest.
- No protest accompanied the payment of additional search fees.
